DETAILED ACTION

Claim Rejections -35 USC § 103

The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

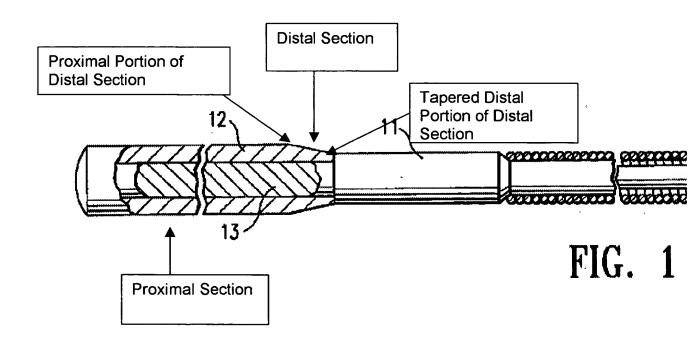

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

Claims 1-10, 13-25, 26, and 27 are rejected under 35 U.S.C. 103(a) as being unpatentable over Fariabi (US 5,636,641) in view of Fagan (US 5,720,300) (See diagram below). Fariabi teaches a heat-treated elongate member/guide wire comprising a composite elongate core, the composite elongate core formed in part of an aged hardened material and in part of a superelastic material, wherein the aged hardened material and superelastic material extend from the proximal section to the tapered distal section, the distal section having a proximal portion and a tapered distal portion, the aged hardened material comprising of at least two materials selected from the group consisting of nickel, cobalt, molybdenum, chromium, tungsten, and iron (Column 3, Lines 49-51, 64-65). Fariabi does not teach that the elongate core is formed in part of a precipitation hardened material and in part of a superelastic material. Fagan teaches of an

Application/Control umber: 09/470,874

Art Unit: 3763

elongate core formed of a precipitation hardened material (Column 4, Lines 54-58). Fagan discloses that in order to avoid kinking of a guidewire it is necessary to have a desirable material that has equal compressive and tensile yield stresses. Such a desirable material, teaches Fagan, is made of a precipitation hardened material (Column 4, Lines 41-58). It would be obvious to one with ordinary skill in the art to use the teachings of Fagan to modify the invention of Fariabi to create a heat-treated elongate member formed at least in part of acomposite elongate core, the composite elongate core formed in part of a precipitation hardened material and in part of a superelastic material, in order to create the necessary stiffness and push provided by the precipitation hardened material of the elongate core member and the desirable flexibility provided by the superelastic material of the elongate core member (Column 5, Lines 65-67; Column 6, Lines 1-10).

Application/Control Imber: 09/470,874

Art Unit: 3763

Fariabi discloses a high strength alloy containing cobalt, nickel, and chromium and particularly to a composite product having a portion formed of the high strength colbalt-nikel-chromium alloy and a portion formed of pseudoelastic alloy such as NiTi alloy (Column 2, lines 16-19). Fariabi further discloses that one embodiment of the invention is an elongated member formed at least in part, of alloy comprising about 28%-65% cobalt, about 2%-40% nickel, about 5%-35% chromium an up to about 12% molybdenum. Other alloying components include up to 20% tungsten, 20% iron and 3% manganese. The alloy may also contain inconsequential amounts of other alloying constituents, as well as impurities, typically less than 0.5% each (Column 2, lines 21-30). Fariabi further states that in another embodiment of the invention, the cobalt-nickel-chromium alloy is formed into a composite structure with a NiTi alloy (Column 2, lines 51-53).

In Figure 1, Fariabi shows the distal section (17) of the core member (11), which is disposed primarily within the coil (14), and is tapered to sequentially smaller diameters to provide gradually increasing flexibility along the length of the distal portion of the guidewire (10). Figure 2 depicts a guidewire (30) with a construction wherein the tapered distal section (31) of the core member (32) extends to the plug (33) which connects the distal end of the core member to the distal end of the helical coil (34) disposed about the distal section of the core

Application/Control umber: 09/470,874

Art Unit: 3763

member. The proximal section (35) of the core member (32) is of composite construction with a sheath (36) of high strength CoNi-Cr alloy and an inner member (37) of a pseudoetastic NiTi alloy. The high strength sheath (36) is removed from the core member to form the tapered distal section (31) to increase the flexibility of the distal section of the guidewire (30).

With regard to claims 2-7, 9, and 10, Fariabi does not teach a composite elongate core having a modulus of elasticity of at least 9,000,000 psi, 12,000,000 psi₁ and 15,000,000 psi and an ultimate tensile strength of at least 150 ksi, 180 ksi, and 200 ksi. Fariabi also does not teach of a precipitation hardenable material such as precipitation hardenable stainless steel and chromium-nickel based single stage martensitic precipitation hardenable stainless steel. Fagan teaches an elongate member (52,56) formed at least in part of a composite elongate core (50) formed at least in part of a precipitation hardened material such as an alloy composed of nickel, cobalt, molybdenum, and chromium (MP35N and Eligiloy) having a small amount of iron (Column 5, lines 2-4), 455PH stainless steel or stainless steel alloy 1 RK91. 455PH is known to be a chromium-nickel based single stage martensitic precipitation hardenable stainless steel (Column 6, lines 1-4; Column 10, lines 36-59). Fagan teaches that these alloys are exemplary because when bent, they will remain elastic through a greater range of stresses than prior guidewires. Since tensile yield stress and compressive yield stress are substantially less disproportionate, compressive

Application/Control mmber: 09/470,874

Art Unit: 3763

failure is delayed, thus enabling the wire to be bent in a sharper curve without permanent deformation (Column 5, Lines 18-59). It would be obvious to one with ordinary skill in the art to use the teachings of Fagan to modify the invention of Fariabi to create a better-performing guidewire that will remain elastic through greater range of stresses. Fagan discloses in Column 10, lines 65-66, that the alloy can have a modulus of elasticity compared to that of type 304 stainless steel (approximately 28,000,000 to 29,000,000 psi.). In addition, the alloy can have a tensile strength as low as about 150 ksi, but preferably about 250 ksi. (Column 10, lines 63-66). Fagan teaches that the modulus of elasticity and the tensile strength depend on the degree to which it is desired to precipitation harden the alloy (Column 11, Lines 5-16) in order to create a guidewire with a smaller diameter without compromising performance. It would be obvious to one with ordinary skill in the art to use the teachings of Fagan to modify the invention of Fariabi in order to create a smaller diameter guidewire for better performance.

Claims 11 and 12 are rejected under 35 U.S.C. 103(a) as being unpatentable over Fariabi in view of Fagan, in further view of Reiss (WO 98/22024). Fariabi and Fagan teach all of the claimed limitations except a precipitation hardenable stainless steel essentially nickel free and a precipitation hardenable stainless steel including less than about 1% nickel. Reiss discloses a guidewire (10) comprising an elongated core element (12) manufactured from a martensitic alloy that is heat-treated to render a fully hardened core throughout

Application/Control Imber: 09/470,874

Art Unit: 3763

its cross sectional area (see Abstract). Reiss further discloses examples of temperature hardened, martensitic steel alloys such as carbon, manganese, chromium, silicone, molybdenum, iron, and nickel. As can be seen from page 7, Table II, line 9, the amount of nickel that can be used is negligible or in other words, essentially nickel-free or containing less than about 1% nickel. Reiss teaches nickel to be one of the hardened alloys used in guidewires having a hardened core having the characteristic of superior torsional control or torque transmission (Page 6, Lines 30-32 and Page 1, Lines 6-8). It would be obvious to one with ordinary skill in the art to use the teachings of Reiss to modify the invention of Fariabi and Fagan to create a guidewire that is essentially nickel-free or contains less than about 1% nickel in order for the guidewire to perform with superior torsional control or torque transmission.

Conclusion

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Kathryn L Thompson whose telephone

Art Unit: 3763

number is 703-305-3286. The examiner can normally be reached on 8:30 AM - 6:00 PM: 1st Friday Off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Brian Casler can be reached on 703-308-3552. The fax phone numbers for the organization where this application or proceeding is assigned are 703-872-9302 for regular communications and 703-872-9303 for After Final communications.

Any inquiry of a general nature or relating to the status of this application or proceeding should be directed to the receptionist whose telephone number is 703-308-0858.
